Heuss Air Improvement Resource, Inc. July 11, 2008

Les Grant EPA slide 46 and selected text on pages S-10 and S-11 from entire text on pages S-5 to S-32

In 1997, EPA relied heavily on two cohort studies, the Six-City study⁶ and the ACS study⁷ that reported associations of fine PM and sulfate with cardiopulmonary deaths. In a careful re-analysis of these two studies a Health Effects Institute (HEI)-sponsored team⁸ replicated the results that show an increased risk in the range of 7 to 14 % for all-cause mortality and 12 to 19 % for cardiopulmonary mortality associated with a 10 µg/m³ increase in PM2.5. However, the re-analysis also showed that 1) the increased risk was cardiovascular not respiratory, 2) one gaseous pollutant, SO2, had a strong association with mortality, 3) when SO2 was included in the model the PM all-cause mortality association was materially reduced and became non-significant, 4) the increased mortality was experienced in the portion of the cohort that had a high school education or less, and 5) there was a significant spatial heterogeneity in the association, with no effect seen in western U. S. cities. ⁹ All these additional findings raise questions concerning the interpretation of the PM2.5 associations as a universally applicable chronic PM health effect caused by generic PM2.5.
